### Electricity Data and Mathematical Price Models

What model for such a behavior ?

6 years of data: **AESO SP prices** (Alberta, Canada), Apr. 7 2001 - Apr. 6 2007, including **electricity demand**.

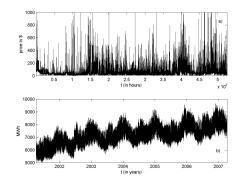

Figure 1: Prices and demand in the Alberta power market: 5 years from Apr-7-2001 to Apr-6-2007, time in hours; a) prices, b) demand

### Simple Model, Complex Behaviour

A model that:

- includes energy demand
- in continuous time supports spikes without jumps
- has a rich phenomenology, as that seen in data
- has some microeconomic foundations
- in discrete time belongs to a standard class of models (SETARX) and preserves its continuous time properties
- is analyzed in a nonstandard way

### Data

Alberta (Canada) **wholesale power market** (now also retail), a voluntary **pool** (not all energy is traded here).

Data from AESO site:

- energy prices in Canadian dollars
- demand (load) in Megawatt-hour (MWh)

Players:

- gencos
- In the grid (Transmission System Operator, TSO): AESO
- Independent System Operator (ISO) and Exchange: AESO

### Electricity Prices: Spikes Have a Structure

Discrete i-time prices  $\hat{p}_i$  available for **each hour**.

- Hourly demand data is available.
- Spikes appear only during demand crests, but not always.

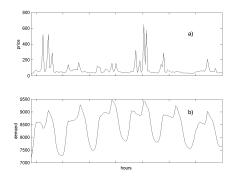

Figure 2: Alberta power market: one week from Mon Jan-08-2007 to Sun Jan-14-2007, time in hours; a) system prices in C\$, b) demand in a co

### **Spikes and Baseline**

Spikes originate from a first mean reversion mechanism.

In their **baselines**, prices follow smoothly the demand daily seasonality - a second mean reversion type.

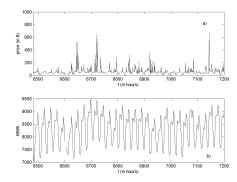

Figure 3: Alberta power market: one month from Jan-1-2007 to Jan-31-2007, time in hours; a) prices, b) demand

### Logprices and Antispikes

Prices p show spikes, logprices  $x = \log p$  show spikes and **antispikes**, with a mean reversion similar to the spikes mean reversion.

Logprices baseline has yearly periodicity. Third mean reversion type.

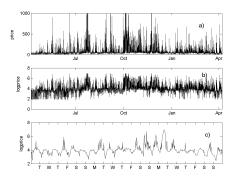

Figure 4: Alberta power market; a) one year of prices, from hour 1 of Apr-07-2006 to hour 24 of Apr-07-2007; b) logprices, same scale; c) detail of b): 3 weeks of logprices from hour 1 of Aug-14 to hour 24 of Sep-3.

### Periodic Parossistic Phases

There are seasons in which demand triggers higher frequency spiking (e.g. winter)

#### This is a second type of seasonality: **spikes don't change in structure but become more frequent**

## Fourth mean reversion type.

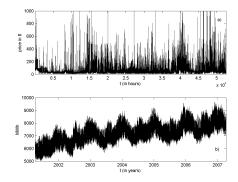

Figure 5: Prices and demand in the Alberta power market: 5 years from Apr-7-2001 to Apr-6-2007, time in hours; a) prices, b) demand

### **Modelling Approaches**

- Top-down: the standard financial way.
- Bottom-up: agents on networks.
- **Hybrid**: take in consideration microeconomics, use few degrees of freedom.

### Power Markets as Tight Markets

Features that make power markets different from stock markets:

- A Rigid Periodic demand d(t) drives prices p: p = p(d(t))
- Capacity constraints affect prices
- Grid constraints affect prices
- Anticipated constrained times are the best times to game the system...

Being **potentially constrained**, the power market sometimes becomes a **tight market** 

### The Threshold

Technical constraints introduce a **threshold** in the price formation mechanism

- Below the threshold prices react smoothly to demand variations
- Above the threshold prices can react in a non-smooth way.

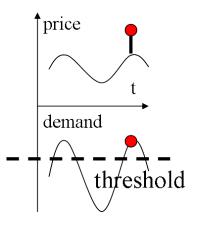

Figure 6: Threshold effects

### Some Stochastic Financial Models

Continuous-Time (from high frequency finance):

- Jump-diffusion: compound Poisson, Lévy.
- Nonlinear pure diffusion: *Resonating Market Models*, Lucheroni 2007.

Discrete-Time (more natural, since data are discrete):

- **ARX**: driven linear autoregressions.
- Switching ARX.
- TARX: SETARX models for spikes and antispikes Lucheroni 2010.

(I) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1)) < ((1))

### SETARX Models

**Discrete-Time** 

• **AR(M)X**:  $L^h x_i = x_{i-h}, \phi^M(L) = 1 - \ldots - \phi_M L^M$ 

$$\{\phi^{M}(L) \mathbf{x}_{i} = \sigma \varepsilon_{i} + \mathbf{d}_{i-1}$$

• Switching ARX: 2 regimes R, 1 threshold T

$$\begin{cases} \phi_l^2(L) x_i = \sigma \varepsilon_i + d_{i-1}, & u(i) \ge T \quad (R = I) \\ \phi_{II}^2(L) x_i = \sigma \varepsilon_i + d_{i-1}, & u(i) < T \quad (R = II) \end{cases}$$

• 
$$u(i) = U(x_i) \rightarrow \textbf{SETARX}$$

-

4 D K 4 B K 4 B K 4 B K

### The McKean Oscillator

Discrete or continous-time. Two coupled nonlinear diffusions *x* and *y*. 2 **thresholds**  $D_L$  and  $D_R$ , then 3 **regimes**. Forcing *f*. Noise  $\xi = dW/dt$ .

$$\begin{aligned} \epsilon \dot{x} &= g_R(x; a) - y \\ \dot{y} &= x - \gamma_b y + b + f(t) + \sigma(d) \xi(t) \end{aligned}$$

where  $g_R(x; D_L, D_R) =$ 

$$\begin{cases} -\beta_L(x+D_L)-\gamma_0D_L, & -\infty < x \le -D_L \quad (I) \\ \gamma_0x, & -D_L < x < D_R \quad (II) \\ -\beta_R(x-D_R)+\gamma_0D_R, & D_R \le x < +\infty \quad (III) \end{cases}$$

### f = 0: No Forcing

## For forcing f = 0, **no** seasonality is included.

**Logprice** x(t).

Price 
$$p(t) = e^{x(t)}$$
.

Spikes with different heights and widths, springing from a constant baseline mean reversion level.

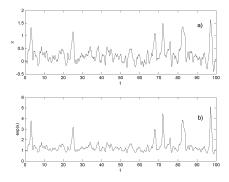

Figure 7: McKean model (from new form). Parameters:  $\epsilon = 0.3$ , d = 0.1, a = 1, b = -0.5,  $\gamma_b = 1$ . a) logprice x(t) dynamics, b) price  $p(t) = \exp x(t)$  dynamics.

### McKean Oscillator at f = 0

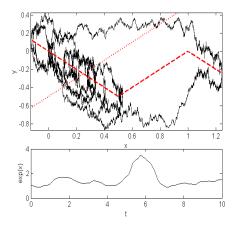

Phase space  $\{x(t), y(t)\}.$ 

Nullclines: x for  $\dot{x} = 0$ , y for  $\dot{y} = 0$ .

**Logprice** x(t).

Auxiliary coordinate y(t).

$$0 << \epsilon < 1$$
 (soft regime)

**A b** 

### **Dynamically-Critical Points**

The McKean model undergoes a **subcritical** Hopf transition as *b* changes. Spikes can be formed close to  $b_2$ , **subthreshold**, as **stochastic orbits**.

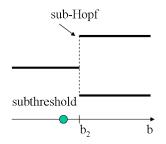

Figure 8: FNS model, x dynamic range

### $f \neq 0$ : SRS

# Forcing $f(t) = A \sin(\omega t)$ , to include **daily baseline** seasonality.

Stochastically resonating spiking -SRS (second mean reversion type).

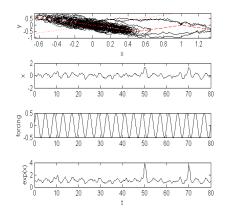

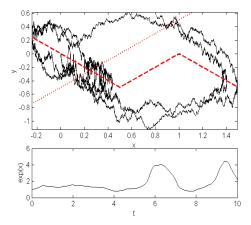

Figure 9: McKean model.  $\epsilon = 0.3, d = 0.1, b = 0, \gamma_b = 1, A = 0.5, \omega = \pi/2.$  a)

#### Movie: Resonating Power Market

Stable, unstable, metastable regions.

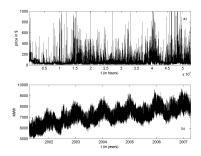

ロト 4 個 ト 4 臣 ト 4 臣 ト 三臣 - わへで

### **Two Frequencies: Parossistic Phases**

- periodic 'fountains' of spikes
- demand: only 2 frequencies (more can be added), no trend
- fourth mean reversion type

$$f(t) = u\left(v\sin(\frac{\omega_f}{365}t) + \sin(\omega_f t)\right)$$

### **Real and Simulated Series**

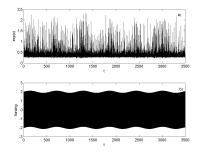

Figure 11: Simulation of 6 years of power market prices, extended model for  $\epsilon = 0.15$ ,  $\kappa = 1$ ,  $\lambda = 1$ , b = 0,  $\gamma = 1$ ,  $\xi = 2$ , c = -1, fwith u = 2, v = 0.06,  $\omega_f = 4$ , d = 0.1,  $\Delta t = 0.035$ ; a) price process ; b) forcing: the smaller yearly  $\omega_f/365$  frequency modulates the much higher daily  $\omega_f$  frequency, which cannot be resolved in the picture.

### Antispikes: SAS McKean

**Spike-AntiSpike McKean Model** (SAS): 5 regimes plus forcing (*L* for left, *R* for right).

$$\begin{aligned} \epsilon \dot{x} &= g_R^{SAS}(x; C_L, C_R) - y \\ \dot{y} &= x - \gamma_b y + b + f(t) + \sigma(d) \xi(t) \end{aligned}$$

where  $g_R^{SAS}(x; C_L, C_R) =$ 

$$\begin{cases} -\alpha_{L}(x+C_{L}), & -\infty & < x \leq -C_{L} & (I) \\ \beta_{L}(x+C_{L}), & -C_{L} & < x < -D_{L} = -\frac{\beta_{L}}{\gamma_{0}+\beta_{L}}C_{L} & (II) \\ -\gamma_{0}x, & -D_{L} & \le x \leq -D_{R} = \frac{\beta_{R}}{\gamma_{0}+\beta_{R}}C_{R} & (III) \\ \beta_{R}(x-D_{R}), & D_{R} & < x < -C_{R} & (IV) \\ -\alpha_{R}(x-D_{R}), & C_{R} & \le x < +\infty & (V) \end{cases}$$

### SAS McKean Dynamics

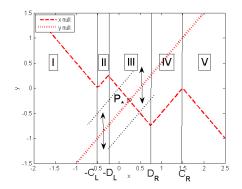

Figure 12: SAS McKean model phase-space for f = 0. Other parameters:  $\alpha_L = \alpha_R = 1$ ,  $\beta_L = \beta_R = 1$ ,  $\gamma_0 = 1$ ,  $C_L = 1/2$ ,  $C_R = 3/2$ , b = -1/2,  $\gamma_b = 1$ .

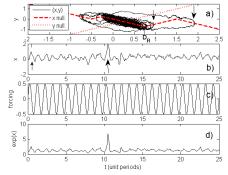

Figure 13: SAS McKean model for  $f \neq 0$ . Parameters:  $\epsilon = 0.3$ , s = 0.1,  $\alpha_L = \alpha_R = 1$ ,  $\beta_L = \beta_R = 1$ ,  $\gamma_0 = 1$ ,  $C_L = 1/2$ ,  $C_R = 3/2$ , b = -1/2,  $\gamma_b = 1$ , A = 0.5,  $\omega_0 = \pi/2$ .

### **Changes of Baseline**

$$\left\{ egin{array}{ll} -eta_L(x+D_L)-\gamma_0D_L+eta_L\Sigma(t),\ -\infty< x\leq -D_L+\Sigma(t),\ R=R_1\ \gamma_0x-\gamma_0\Sigma(t),\ -D_L+\Sigma(t)< x< D_R+\Sigma(t),\ R=R_2\ -eta_R(x-D_R)+\gamma_0D_R+eta_R\Sigma(t),\ D_R+\Sigma(t)\leq x<+\infty,\ R=R_3. \end{array} 
ight.$$

Third mean reversion type.

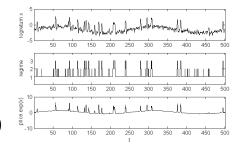

Figure 14: Floating McKean model for f = 0. Parameters:  $\epsilon = 0.5$ , s = 0.4,  $\beta_L = 1$ ,  $\beta_R = 1$ ,  $\gamma_0 = 1$ ,  $D_L = D_R = \Delta = 1$ , b = 1,  $\gamma_b = 1$ ,  $A_s = 1$ ,  $\omega_s = 2\pi/250$ , dt = 0.01. a) logprice x(t) dynamics, b) regime dynamics, d) price dynamics.

### Calibration for f = 0

$$L = -\frac{N-1}{2} \ln(2\pi\sigma^{2}/\Delta t) - \frac{\Delta t}{2\sigma^{2}} \sum_{n=2}^{N} (\Omega_{R}(n+1,n))^{2};$$
  

$$\Omega_{R}(n+1,n) = \sum_{i=1}^{3} \Omega_{R_{i}}(n+1,n) \operatorname{ll}[\hat{x}_{n} \in R_{i}];$$
  

$$\Omega_{R_{i}}(n+1,n) = \epsilon \hat{z}_{n+1} + \epsilon \hat{z}_{n}(1-1/\Delta t) + A_{R}^{1}(n) \beta_{L} + A_{R}^{2}(n) \gamma_{0} + A_{R}^{3}(n) \beta_{R} + A_{R}^{4}(n) \gamma_{b} + A_{R}^{5}(n) b;$$
  

$$C\Theta = -V$$

$$\Theta = \{\beta_L, \gamma_0, \beta_R, \gamma_b, b\}; \quad C_k^j = (\sum_{n=2}^N A_R^k A_R^j);$$
$$V^j = (\epsilon \hat{z}_{n+1} + \epsilon \hat{z}_n (1 - 1/\Delta t)) \sum_{n=2}^N A_R^j(n)$$

2

イロト イポト イヨト イヨト

### Summary 1

The model set includes **complex mean reversion** for:

- spikes and antispikes (Hopf bifurcations)
- baseline prices daily periodicity (forcing at daily frequency)
- baseline prices yearly seasonality (rigid displacement)
- Irequency seasonality (second lower frequency in forcing)

### Summary 2

A model for prices of spot power markets is discussed, that

- takes into account fundamental market microeconomic features
- incorporates naturally an intrinsic threshold
- uses a single mechanism to model short and long term mean reversion
- exploits critical point analysis
- uses only one source of noise
- can be easily calibrated at hour scales
- consists actually of a set of models

### The most exciting phrase to hear in Science is not "Eureka", but "That's funny" !

Isaac Asimov
